Marketing campaign test report

Conversion rates and lift

The marketing team ran a live test to see if the new ad drives more orders than the standard public service ad.

The test ran across both groups. The baseline group saw a conversion rate of 1.78%. The group exposed to the new ad converted at 2.55%.

The ad produced an absolute lift of 0.77 percentage points. That equals a relative lift of 43.09%. For every 1,000 people who view the ad, about 8 more make a purchase than would under the baseline ad. The ad clearly increased buyer response across the test pool.

Statistical proof

The split produced clear numbers.

The two-sample test gave a z-statistic of 7.3701 with a p-value of 1.71e-13. The chi-square test gave a test statistic of 54.0058 with a p-value of 2.00e-13.

With the alpha = 0.01, both p-values sit well below that line. A z-score above 7 means the gap sits more than 7 standard deviations away from pure chance.

With Absolute Lift: 0.769% and Relative Lift: 43.09%, so the lift was real. It was not random noise. The team can roll out the new ad to all users without risk of an accidental false read.
